# Computations within a functor context: Combining monads

Programs often need to combine monadic effects

- "Effect" $\equiv$ what else happens in $A \Rightarrow M^B$ besides computing $B$ from $A$
- Examples of effects for some standard monads:
  - `Option` – computation will have no result or a single result
  - `List` – computation will have zero, one, or multiple results
  - `Either` – computation may fail to obtain its result, reports error
  - `Reader` – computation needs to read an external context value
  - `Writer` – some value will be appended to a (monoidal) accumulator
  - `Future` – computation will be scheduled to run later
- How to combine several effects in the same functor block (`for`/`yield`)?

```
// This is not valid Scala!
val result = for { i ← 1 to n
   j ← Future { q(i) }
   k ← maybeError(j) : Try[Int]
} yield f(k)
// What should be the type of result??
```

```
// This is not valid Scala!
(1 to n).flatMap { i ⇒
   Future(q(i)).flatMap { j ⇒
     maybeError(j).map { k ⇒
       f(k)
     }}}
```

- The code will work if we "unify" all effects in a new, larger monad
- Need to compute the type of new monad that contains all given effects

# Combining monadic effects I. Trial and error

There are several ways of combining two monads into a new monad:

- If $M_1^A$ and $M_2^A$ are monads then $M_1^A \times M_2^A$ is also a monad
  - But $M_1^A \times M_2^A$ describes two separate values with two separate effects
- If $M_1^A$ and $M_2^A$ are monads then $M_1^A + M_2^A$ is usually not a monad
  - If it worked, it would be a choice between two different values / effects
- If $M_1^A$ and $M_2^A$ are monads then one of $M_1^{M_2^A}$ or $M_2^{M_1^A}$ is often a monad
- Examples and counterexamples for functor composition:
  - Combine $Z \Rightarrow A$ and $\text{List}^A$ as $Z \Rightarrow \text{List}^A$
  - Combine `Future[A]` and `Option[A]` as `Future[Option[A]]`
  - But `Either[Z, Future[A]]` and `Option[Z ⇒ A]` are not monads
  - Neither `Future[State[A]]` nor `State[Future[A]]` are monads
- The order of effects matters when composition works both ways:
  - Combine `Either` ($M_1^A = Z + A$) and `Writer` ($M_2^A = W \times A$)
    - ★ as $Z + W \times A$ – either compute result and write a message, or all fails
    - ★ as $(Z + A) \times W$ – message is always written, but computation may fail
- Find a general way of defining a new monad with combined effects
- Derive properties required for the new monad

# Combining monadic effects II. Lifting into a larger monad

If a "big monad" `BigM[A]` *somehow* combines all the needed effects:

```
// This could be valid Scala...
val result: BigM[Int] = for {
  i ← lift₁(1 to n)
  j ← lift₂(Future{ q(i) })
  k ← lift₃(maybeError(j))
} yield f(k)
```

```
// If we define the various
// required "lifting" functions:
def lift₁[A]: Seq[A] ⇒ BigM[A] = ???
def lift₂[A]: Future[A] ⇒ BigM[A] = ???
def lift₃[A]: Try[A] ⇒ BigM[A] = ???
```

- Example 1: combining as `BigM[A] = Future[Option[A]]` with liftings:

```
def lift₁[A]: Option[A] ⇒ Future[Option[A]] = Future.successful(_)
def lift₂[A]: Future[A] ⇒ Future[Option[A]] = _.map(x ⇒ Some(x))
```

- Example 2: combining as `BigM[A] = List[Try[A]]` with liftings:

```
def lift₁[A]: Try[A] ⇒ List[Try[A]] = x ⇒ List(x)
def lift₂[A]: List[A] ⇒ List[Try[A]] = _.map(x ⇒ Success(x))
```

Remains to be understood:

- Finding suitable laws for the liftings; checking that the laws hold
- Building a "big monad" out of "smaller" ones, with lawful liftings
  - Is this always possible? Unique? Are there alternative solutions?
- Ways of reducing the complexity of code; make liftings automatic

# Laws for monad liftings I. Identity laws

Whatever identities we expect to hold for monadic programs must continue to hold after lifting `M1` or `M2` values into the "big monad" `BigM`

- We assume that `M1`, `M2`, and `BigM` already satisfy all the monad laws

Consider the various functor block constructions containing the liftings:

- Left identity law after `lift1`

```
// Anywhere inside a for/yield:          // Must be equivalent to...
i ← lift1(M1.pure(x))                    i = x
j ← bigM(i) // Any BigM value.           j ← bigM(x)
```

`lift1(M1.pure(x)).flatMap(b) = b(x)` — in terms of Kleisli composition ($\diamond$):

$(\text{pure}_{M_1} \fatsemi \text{lift}_1)^{:X \Rightarrow \text{BigM}^X} \diamond b^{:X \Rightarrow \text{BigM}^Y} = b$ with $f^{:X \Rightarrow M^Y} \diamond g^{:Y \Rightarrow M^Z} \equiv x \Rightarrow f(x).\text{flatMap}(g)$

- Right identity law after `lift1`

```
// Anywhere inside a for/yield:          // Must be equivalent to...
x ← bigM // Any BigM value.              x ← bigM
i ← lift1(M1.pure(x))                    i = x
```

`b.flatMap(M1.pure andThen lift1) = b` — in terms of Kleisli composition:

$$b^{:X \Rightarrow \text{BigM}^Y} \diamond (\text{pure}_{M_1} \fatsemi \text{lift}_1)^{:Y \Rightarrow \text{BigM}^Y} = b$$

- The same identity laws must hold for `M2` and `lift2` as well

# Laws for monad liftings II. Simplifying the laws

$\left(\text{pure}_{M_1} \fatsemi \text{lift}_1\right)$ is a unit for the Kleisli composition $\diamond$ in the monad `BigM`

- But the monad `BigM` already has a unit element, namely $\text{pure}_{\text{BigM}}$
- The two-sided unit element is always unique: $u = u \diamond u' = u'$
- So the two identity laws for $\left(\text{pure}_{M_1} \fatsemi \text{lift}_1\right)$ can be reduced to one law:

$$\text{pure}_{M_1} \fatsemi \text{lift}_1 = \text{pure}_{\text{BigM}}$$

Refactoring a portion of a monadic program under `lift1` gives another law:

```
// Anywhere inside a for/yield, this...
i ← lift1(p) // Any M1 value.
j ← lift1(q(i)) // Any M1 value.
```

```
// must be equivalent to...
pq = p.flatMap(q) // In M1.
j ← lift1(pq) // Now lift it.
```

```
lift1(p).flatMap(q andThen lift1) = lift1(p flatMap q)
```

- Rewritten equivalently through $\text{flm}_M : \left(A \Rightarrow M^B\right) \Rightarrow M^A \Rightarrow M^B$ as

$\text{lift}_1 \fatsemi \text{flm}_{\text{BigM}}\left(q \fatsemi \text{lift}_1\right) = \text{flm}_{M_1} q \fatsemi \text{lift}_1$ – both sides are functions $M_1^A \Rightarrow \text{BigM}^B$

- Rewritten equivalently through $\text{ftn}_M : M^{M^A} \Rightarrow M^A$ as

$\text{lift}_1 \fatsemi \text{fmap}_{\text{BigM}} \text{lift}_1 \fatsemi \text{ftn}_{\text{BigM}} = \text{ftn}_{M_1} \fatsemi \text{lift}_1$ – both sides are functions $M_1^{M_1^A} \Rightarrow \text{BigM}^A$

- Rewritten equivalently in terms of Kleisli composition $\diamond_M$ as

$$\left(b^{:X \Rightarrow M_1^Y} \fatsemi \text{lift}_1\right) \diamond_{\text{BigM}} \left(c^{:Y \Rightarrow M_1^Z} \fatsemi \text{lift}_1\right) = \left(b \diamond_{M_1} c\right) \fatsemi \text{lift}_1$$

- Liftings $\text{lift}_1$ and $\text{lift}_2$ must obey an identity law and a composition law
  - The laws say that the liftings **commute with** the monads' operations

# Laws for monad liftings III. The naturality law

Show that $\mathsf{lift}_1 : M_1^A \Rightarrow \mathrm{BigM}^A$ is a natural transformation

- It maps $\mathsf{pure}_{M_1}$ to $\mathsf{pure}_{\mathrm{BigM}}$ and $\mathsf{flm}_{M_1}$ to $\mathsf{flm}_{\mathrm{BigM}}$
  - $\mathsf{lift}_1$ is a **monadic morphism** between monads $M_1^\bullet$ and $\mathrm{BigM}^\bullet$

The (functor) naturality law: for any $f : X \Rightarrow Y$,

$$\mathsf{lift}_1 ; \mathsf{fmap}_{\mathrm{BigM}} f = \mathsf{fmap}_{M_1} f ; \mathsf{lift}_1$$

$$\begin{array}{ccc} M_1^X & \xrightarrow{\mathsf{lift}_1} & \mathrm{BigM}^X \\ {\scriptstyle \mathsf{fmap}_{M_1}\ f^{:X\Rightarrow Y}}\downarrow & & \downarrow{\scriptstyle \mathsf{fmap}_{\mathrm{BigM}}\ f^{:X\Rightarrow Y}} \\ M_1^Y & \xrightarrow{\mathsf{lift}_1} & \mathrm{BigM}^Y \end{array}$$

Derivation of the naturality law:

- Express fmap as $\mathsf{fmap}_M f = \mathsf{flm}_M (f ; \mathsf{pure}_M)$ for both monads
- Given $f^{:X\Rightarrow Y}$, use the law $\mathsf{flm}_{M_1} q ; \mathsf{lift}_1 = \mathsf{lift}_1 ; \mathsf{flm}_{\mathrm{BigM}} (q ; \mathsf{lift}_1)$ to compute $\mathsf{flm}_{M_1} (f ; \mathsf{pure}_{M_1}) ; \mathsf{lift}_1 = \mathsf{lift}_1 ; \mathsf{flm} (f ; \mathsf{pure}_{M_1} ; \mathsf{lift}_1) = \mathsf{lift}_1 ; \mathsf{flm} (f ; \mathsf{pure}_{\mathrm{BigM}}) = \mathsf{lift}_1 ; \mathsf{fmap}_{\mathrm{BigM}} f$

A monadic morphism is always also a natural transformation of the functors

# Monad transformers I: Motivation

- Combine $Z \Rightarrow A$ and $1 + A$: only $Z \Rightarrow 1 + A$ works, not $1 + (Z \Rightarrow A)$
  - It is not possible to combine monads via a natural bifunctor $B^{M_1, M_2}$
  - It is not possible to combine arbitrary monads as $M_1^{M_2^\bullet}$ or $M_2^{M_1^\bullet}$
    - ⋆ Example: state monad $\text{St}_S^A \equiv S \Rightarrow A \times S$ does not compose
- The trick: for a fixed **base** monad $L^\bullet$, let $M^\bullet$ (**foreign** monad) vary
- Call the desired result the "$L$'s monad transformer", $T_L^{M,\bullet}$
  - In Scala: `LT[M[_]: Monad, A]` – e.g. `ReaderT`, `StateT`, etc.
- $T_L^{M,\bullet}$ is generic in $M$ but not in $L$
  - No general formula for monad transformers seems to exist
  - For each base monad $L$, a different construction is needed
  - Some monads $L$ do not seem to have a transformer!
- To combine 3 or more monads, compose the transformers: $T_{L_1}^{T_{L_2}^{M,\bullet}}$
  - Example in Scala: `StateT[S, ListT[Reader[R, ?], ?], A]`
- This is called a **monad stack** – but may not be *functor composition*
  - because e.g. `State[S, List[Reader[R, A]]]` is not a monad

# Monad transformers II: The requirements

A **monad transformer** for a **base** monad $L^\bullet$ is a type constructor $T_L^{M,\bullet}$ parameterized by a monad $M^\bullet$, such that for all monads $M^\bullet$

- $T_L^{M,\bullet}$ is a monad (the monad $M$ **transformed with** $T_L$)
- "Lifting" – a monadic morphism $\text{lift}_L^M : M^A \rightsquigarrow T_L^{M,A}$, natural in $M^\bullet$
- "Base lifting" – a monadic morphism $\text{blift} : L^A \rightsquigarrow T_L^{M,A}$
  - The "base lifting" could not possibly be natural in $L^\bullet$
- Transformed identity monad (Id) must be $L$, i.e. $T_L^{\text{Id},\bullet} \cong L^\bullet$
- $T_L^{M,\bullet}$ is **monadically natural** in $M^\bullet$ (but not in $L^\bullet$)
  - $T_L^{M,\bullet}$ is natural w.r.t. a monadic functor $M^\bullet$ as a type parameter
  - For any monad $N^\bullet$ and a monadic morphism $f : M^\bullet \rightsquigarrow N^\bullet$ we need to have a monadic morphism $T_L^{M,\bullet} \rightsquigarrow T_L^{N,\bullet}$ for the transformed monads
    - ★ If we implement $T_L^{M,\bullet}$ only via $M$'s monad methods, naturality will hold
  - Cf. `traverse`: $L^A \Rightarrow (A \Rightarrow F^B) \Rightarrow F^{L^B}$ – natural w.r.t. applicative $F^\bullet$
  - This is needed for lifting a "runner" $M^A \rightsquigarrow A$ to $T_L^{M,\bullet} \rightsquigarrow T_L^{\text{Id},\bullet} = L^\bullet$
- "Base runner": lifts $L^A \rightsquigarrow A$ into a monadic morphism $T_L^{M,\bullet} \rightsquigarrow M^\bullet$

# Monad transformers III: First examples

Recall these monad constructions:

- If $M^A$ is a monad then $R \Rightarrow M^A$ is also a monad (for a fixed type $R$)
- If $M^A$ is a monad then $M^{Z+A\times W}$ is also a monad (for fixed $W$, $Z$)

This gives the monad transformers for base monads `Reader`, `Writer`, `Either`:

```
type ReaderT[R, M[_], A] = R ⇒ M[A]
type EitherT[Z, M[_], A] = M[Either[Z, A]]
type WriterT[W, M[_], A] = M[(W, A)]
```

- `ReaderT` wraps the foreign monad from the outside
- `EitherT` and `WriterT` require the foreign monad to wrap *them* outside

Remaining questions:

- What are transformers for other standard monads (`List`, `State`, `Cont`)?
  - These monads do not compose (neither "inside" nor "outside" works)
- How to derive a monad transformer for an arbitrary given monad?
  - For monads obtained via known monad constructions?
  - For monads constructed via other monad transformers?
  - Is it always possible? (Probably not.)
- For a given monad, is the corresponding monad transformer unique?
- How to avoid the boilerplate around `lift`? (`mtl`-style transformers)

# Monad transformers IV: The zoology of monads

Need to select the correct monad transformer construction, per monad:

- "Composed-inside", base monad is inside foreign monad: $T_L^{M,A} = M^{L^A}$
  - Examples: `OptionT`, `WriterT`, `EitherT`
- "Composed-outside", base monad is outside: $T_L^{M,A} = L^{M^A}$
  - Examples: `ReaderT`; `SearchT` for search monad `S[A] = (A ⇒ Z) ⇒ A`
  - More generally: all rigid monads have "outside" transformers
    - ★ Definition: a **rigid monad** has the method `fuseIn`: $\left(A \Rightarrow R^B\right) \Rightarrow R^{A \Rightarrow B}$
- "Recursive": interleaves the base monad and the foreign monad
  - Examples: `ListT`, `NonEmptyListT`, `FreeMonadT`
- "Irregular": none of the above constructions work
  - Examples: `StateT`, `ContT`, "codensity monads" (no full transformers)
- Examples of monads for which no transformers are available
  - Pointed reader $R_Z^A \equiv A + (Z \Rightarrow A)$; selector $S_{P,Q}^A \equiv \left(A \Rightarrow P^Q\right) \Rightarrow P^A$
- Monad constructions: making a transformer for new monads
  - Product monads $M^A \times N^A$ – have the "product transformer"
  - Consumer choice monads $H^A \Rightarrow A$ – have the "outside" transformer
  - Free pointed monads $A + M^A$ – have no transformer

# Rigid monads, their laws and structure

- A **rigid monad** has the method `fuseIn`: $\left(A \Rightarrow R^B\right) \Rightarrow R^{A \Rightarrow B}$
  - Any functor has the method `fuseOut`: $R^{A \Rightarrow B} \Rightarrow A \Rightarrow R^B$

# Invalid attempts to create a general monad transformer

General recipes for combining two functors $L^\bullet$ and $M^\bullet$ all fail

- Functor composition: $L^{M^\bullet}$, $M^{L^\bullet}$ – not a monad for some $L^\bullet$, $M^\bullet$
- Making a monad out of functor composition:
  - free monad over $L^{M^\bullet}$: $F^A \equiv A + L^{M^{F^A}}$ – `lift` violates identity law
  - codensity monad over $L^{M^\bullet}$: $F^A \equiv \forall B.\, (A \Rightarrow L^{M^B}) \Rightarrow L^{M^B}$ – no `lift`
- Codensity-$L$ transformer: $\text{Cod}_L^{M,A} \equiv \forall B.\, (A \Rightarrow L^B) \Rightarrow L^{M^B}$ – no `lift`
  - uses the continuation transformer on $M^A \cong \forall B.\, (A \Rightarrow B) \Rightarrow M^B$
- Codensity composition: $F^A \equiv \forall B.\, (M^A \Rightarrow L^B) \Rightarrow L^B$ – not a monad
  - Counterexample: $M^A \equiv R \Rightarrow A$ and $L^A \equiv S \Rightarrow A$
- "Monoidal" convolution: $F^A \equiv \exists P \exists Q.\, (P \times Q \Rightarrow A) \times L^P \times M^Q$
  - combines functors via $L^A \cong \exists P. L^P \times (P \Rightarrow A)$ and same for $M^\bullet$
  - not a monad for some $L^\bullet$, $M^\bullet$
- "Fake" transformers: $T_L^{M,A} \equiv L^A$; or $T_L^{M,A} \equiv M^A$; or just $T_L^{M,A} \equiv 1$
  - no `lift` and/or no base runner and/or $T_L^{\text{Id},A} \not\equiv L^A$

# Exercises

1. Show that the method `pure`: $A \Rightarrow M^A$ is a monadic morphism between monads $\mathrm{Id}^A \equiv A$ and $M^A$.
2. Show that $M_1^A + M_2^A$ is *not* a monad when $M_1^A \equiv 1 + A$ and $M_2^A \equiv Z \Rightarrow A$.
3. Derive the composition law for `lift` in the form $\mathsf{lift}_1 \fatsemi \mathsf{fmap}_{\mathsf{BigM}} \mathsf{lift}_1 \fatsemi \mathsf{ftn}_{\mathsf{BigM}} = \mathsf{ftn}_{M_\mathbf{1}} \fatsemi \mathsf{lift}_1$ from $\mathsf{lift}_1 \fatsemi \mathsf{flm}_{\mathsf{BigM}}\,(q \fatsemi \mathsf{lift}_1) = \mathsf{flm}_{M_\mathbf{1}}\, q \fatsemi \mathsf{lift}_1$. Draw type diagrams for both laws.
